

Higher-Order Functions

Slides adapted from Berkeley CS61a

Higher-Order Functions

Functions are **first-class**, meaning they can be manipulated as values

A **higher-order function** is:

A function that takes a function as an argument

and/or

A function that returns a function as a return value

Generalization

Generalizing Patterns with Arguments

Regular geometric shapes relate length and area.

Shape:

Area:

$$r^2$$

$$\pi \cdot r^2$$

$$\frac{3\sqrt{3}}{2} \cdot r^2$$

Generalizing Patterns with Arguments

Regular geometric shapes relate length and area.

Shape:

Area:

$$1 \cdot r^2$$

$$\pi \cdot r^2$$

$$\frac{3\sqrt{3}}{2} \cdot r^2$$

Finding common structure allows for shared implementation

Higher-Order Functions

Generalizing Over Computational Processes

The common structure among functions may be a computational process, rather than a number.

$$\sum_{k=1}^5 k = 1 + 2 + 3 + 4 + 5 = 15$$

$$\sum_{k=1}^5 k^3 = 1^3 + 2^3 + 3^3 + 4^3 + 5^3 = 225$$

$$\sum_{k=1}^5 \frac{8}{(4k-3) \cdot (4k-1)} = \frac{8}{3} + \frac{8}{35} + \frac{8}{99} + \frac{8}{195} + \frac{8}{323} = 3.04$$

Summation Example

```
def cube(k):  
    return pow(k, 3)
```

Function of a single argument
(not called "term")

```
def summation(n, term):
```

A formal parameter that will be bound to a
function

```
    """Sum the first n terms of a sequence.
```

```
>>> summation(5, cube)
```

```
225  
"""
```

The cube function is passed as an
argument value

0 + 1 + 8 + 27 + 64 + 125

```
    total, k = 0, 1
```

```
    while k <= n:
```

```
        total, k = total + term(k), k + 1
```

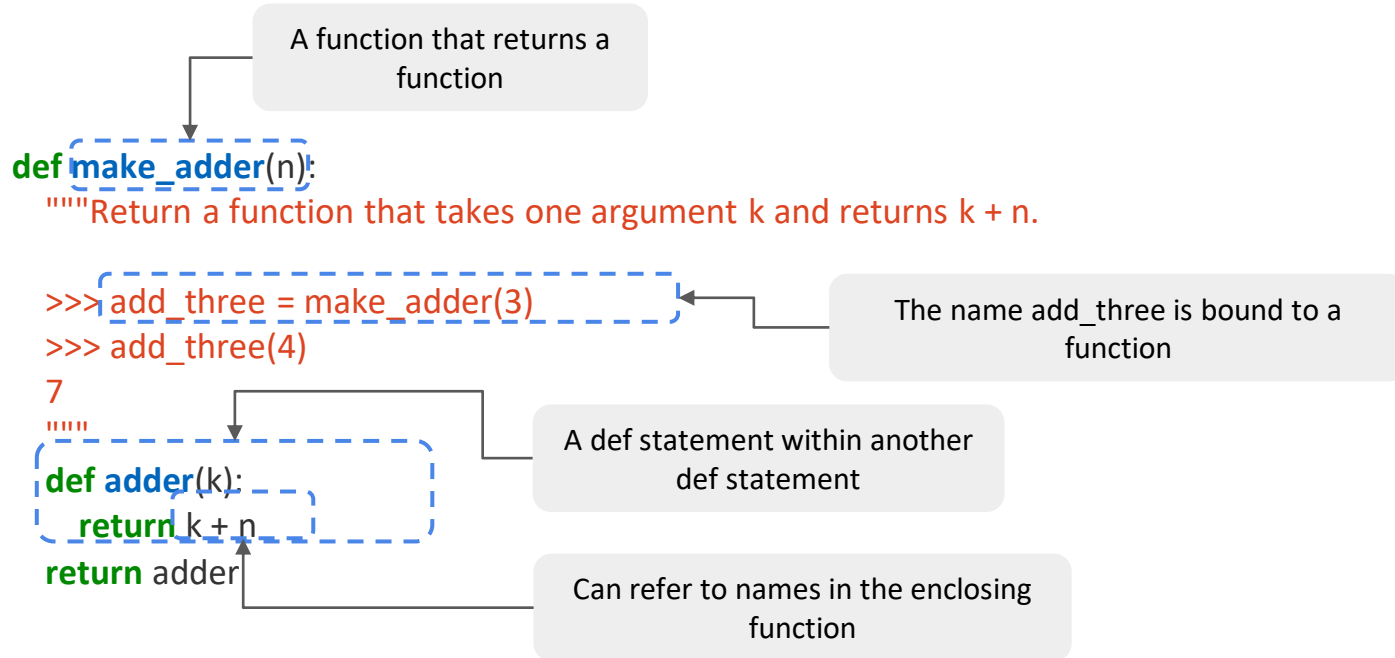

```
    return total
```

The function bound to term gets called
here

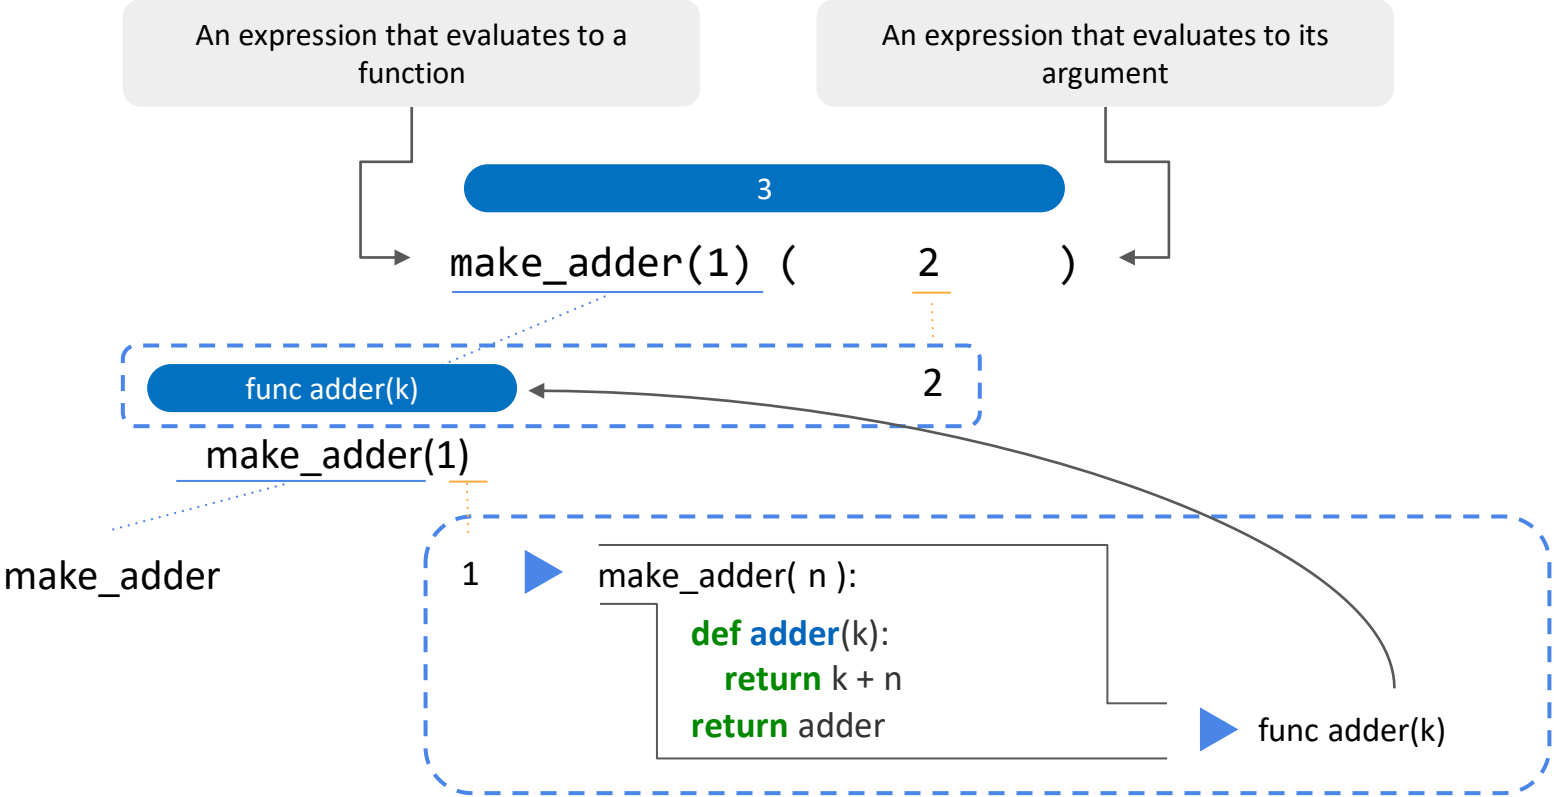

Functions as Return Values

Locally Defined Functions

Functions defined within other function bodies are bound to names in a local frame

Call Expressions as Operator Expressions

Summary

- **Higher-order function**: any function that either accepts a function as an argument and/or returns a function
- Why are these useful?
 - Generalize over different form of computation
 - Helps remove repetitive segments of code
- We saw nested functions (closures) can access variables in outer function through static scoping.

A More Complex Example

```
def make_adder(n):
```

```
    """Return a function that takes one argument k and returns k + n.
```

```
    >>> add_three = make_adder(3)
```

```
    >>> add_three(4)
```

```
    """
```

```
    def adder(k):
```

```
        return k + n
```

```
    return adder
```

```
def square(x):
```

```
    return x * x
```

```
def compose1(f, g):
```

```
    def h(x):
```

```
        return f(g(x))
```

```
    return h
```

```
compose1(square, make_adder(2))(3)
```
